The total return on the GEV is mainly driven by an exceptional financial markets dislocation – a combination of low interest rates, negative equity returns, higher spreads on fixed income securities and high interest rate and equity volatility. A stable operating performance partly offsets these negative impacts and even leads to a positive return in CEE.

Change in Methodology and Assumptions

- § Allowance for Cost for Residual Non-Hedgeable Risk
- § The reference interest rates used for the EEV calculations are based on the corresponding swap rates at December 31, 2008 and include a liquidity spread of 50 bp for all terms
- § Volatilities used to calibrate the economic scenario generator at December 31, 2008 are based on average volatilities over 2008
- § All results shown after minorities and tax
- § GEV allows for all consolidation effects

Comments

- § The NBV represents the value generated by new business sold during the reporting period.
- § The NBV in A/G has decreased due to lower margins on the participating life insurance business as a result of the lower interest rates and higher volatility.
- § The total new business volumes in A/G have not changed relative to the previous year.
- § The total new business volumes in CEE as measured by PVNBP have increased.
- § The NBV in CEE has increased due to higher new business margins.

The increase of NBV in CEE more than offsets the reduction in A/G and leads to an increase of NBV for the group.
